

T.C ADNAN MENDERES UNIVERSITY

Cloud Computing and Virtualization

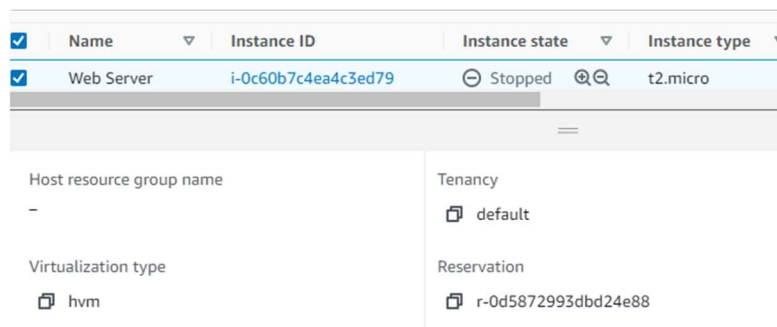

Name – Surname : Betül Berna Soylu

Class : CSE423

Number : 171805019

Homework : Lab-1

(Virtual Machines & Compute Instances)

Exercise-1) Describe the type of virtualization is used by the EC2 instance launched?

- The virtualization type used is HVM.
- Linux Amazon Machine Images uses one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM).
- The main differences between PV and HVM, AMIs are boot methods and whether it will use custom hardware extensions (storage, CPU) for better performance.

	PV	HVM
Description	<ul style="list-style-type: none">• PV AMIs start the boot loop and are then loaded with a special bootloader named PV-GRUB that deactivates the kernel specified in the "menu.lst" file in the image.• Paravirtual guests do not have explicit support for virtualization.	<ul style="list-style-type: none">• HVM AMIs are provided with virtualized hardware set and loaded by running the master boot record of the root block device of the image.• The Amazon EC2 host system brings some or all of the basic hardware available to the user to a similar structure.
Support for hardware extensions	<ul style="list-style-type: none">• No, they cannot use advanced networking or special hardware extensions.	<ul style="list-style-type: none">• HVM users can use hardware extensions that provide quick access to basic hardware in the host system.
Supported instance types	<ul style="list-style-type: none">• Legacy generation instance types support PV AMIs: C1, C3, T1, M1, M2, M3, and HS1.• Current generation instance types do not support PV AMIs.	<ul style="list-style-type: none">• All current generation instance types support HVM AMIs.
Supported Regions	<ul style="list-style-type: none">• Asia Pacific (Tokyo), Asia Pacific (Sydney), Asia Pacific (Singapore), US West (N. California), US East (N. Virginia), US West (Oregon), Europe (Frankfurt), Europe (Ireland)	<ul style="list-style-type: none">• All Regions support HVM instances.

Exercise-2) Create a flask web application that displays the instance meta-data as shown in the following figure (for more info please see <https://github.com/adamchainz/ec2-metadata>).

```
meta veriler                değer  
bu örnek                    i-0c60b7c4ea4c3ed79  
dizini başlatamıyorum      0  
genel ana bilgisayar adı    ec2-54-144-149-69.compute-1.amazonaws.com  
genel IPv4                  54.144.149.69  
Yerel ana bilgisayar adı    IP-172-31-63-175.ec2.internal  
Yerel IPv4                  172.31.63.175
```

Python Code -)

```
from flask import Flask
from ec2_metadata import ec2_metadata
from flask import request

app=Flask(__name__)

@app.route('/')
def hello_world():
    instanceID = ec2_metadata.instance_id
    amiLaunchIndex = ec2_metadata.ami_launch_index
    publicHostname = ec2_metadata.public_hostname
    publicIpv4 = ec2_metadata.public_ipv4
    localHostname = ec2_metadata.private_hostname
    localIpv4 = ec2_metadata.private_ipv4

    resultString = "<table><thead><tr><th>Metadata</th><th>Value</th></tr></thead><tbody><tr><td>instance id</td><td>" + instanceID +
    "</td></tr><tr><td>ami launch index</td><td>" + str(amiLaunchIndex) + "</td></tr><tr><td>public hostname</td><td>" + publicHostname +
    "</td></tr><tr><td>public ipv4</td><td>" + publicIpv4 + "</td></tr><tr><td>local hostname</td><td>" + localHostname +
    "</td></tr><tr><td>local ipv4</td><td>" + localIpv4 + "</td></tr></tbody></table>"

    return resultString

if __name__ == '__main__':
    app.run(host='0.0.0.0',port=5000,debug=True)
```
